

August 27, 2010

Mr. Ken Manning
Chino Basin Watermaster
9641 San Bernardino Road
Rancho Cucamonga, CA 91730

Subject: Annual Streamflow Monitoring Report for Fiscal 2009/10, Water Rights Permit 21225

Dear Mr. Manning:

Wildermuth Environmental, Inc. (WEI) hereby submits the second Annual Streamflow Monitoring Report which was prepared at your direction and pursuant to Term 10 of Watermaster's Water Rights Permit 21225. Per the terms of the March 20, 2007 Stipulation, Watermaster and the California Department of Fish and Game have agreed that Watermaster will prepare estimates of the monthly changes in discharge in each tributary of the Santa Ana River from which stormwater is diverted, prepare annual reports describing the data and methods used to prepare these estimates, and submit these annual reports to the Department of Fish and Game by September 1 of each year. Each annual report will be prepared for the 12-month period running from July 1 through June 30. This report describes the data collected, the methodology for assessing impacts from stormwater diversions, and summarizes the diversion analysis for each tributary system for the period July 1, 2009 through June 30, 2010.

DATA COLLECTION AND METHODOLOGY

There are four main tributary systems to the Santa Ana River from which stormwater and dry-weather discharges are diverted for groundwater recharge: Chino Creek, Cucamonga Creek, Day Creek, and San Sevaine Creek. These creeks, their drainage areas, and other significant hydrologic features are shown in Figure 1.

Two of the four systems, Chino and Cucamonga, are equipped with USGS stream gages from which average daily discharge data are available. The data collected from the USGS gages, stormwater and dry-weather discharge diversions measured and reported by the Inland Empire Utilities Agency (IEUA), and discharge data collected from other known point discharges (e.g. recycled water discharges) are used to estimate the discharge of Chino and Cucamonga Creeks as they enter the Prado Dam Reservoir. These data are also used to reconstruct hydrographs for each tributary as they would have been without the stormwater and dry-weather discharge diversions.

Day Creek and San Sevaine Creek are not equipped with USGS gage stations. In lieu of measured discharge data, the hydrographs for these two systems were estimated using WEI's Waste Load Allocation Model (WLAM). The WLAM uses recharge basin and stream channel characteristics, daily precipitation, boundary inflows, and land use characteristics to collect and route stormwater, non-tributary, and dry-weather discharges through the Santa Ana River Watershed. The WLAM was developed for and is used by the Santa Ana Regional Water Quality Control Board to evaluate volumetric and water quality impacts from existing and planned recycled water discharges to the surface and groundwater resources of the watershed

(WEI, 2009). In addition, Watermaster used the WLAM to develop its Recharge Master Plan and continues to use it to estimate cumulative changes in surface water discharge (WEI, 2010).

Daily discharge tables for key hydrologic components and for the aggregate of hydrologic components have been included in the appendices.

DISCHARGE IMPACT ANALYSIS

During fiscal 2009/10, Watermaster diverted a total of 14,285 acre-feet (acre-ft) of stormwater and dry-weather discharge to spreading basins on the Chino, Cucamonga, Day, and San Sevaine tributary systems. Table 1 summarizes, by tributary, the monthly recharge volumes diverted to each spreading basin. The impacts of these diversions are analyzed below.

Chino Creek

Figure 1 shows the locations of significant points of recharge and discharge on the Chino Creek tributary system, including Watermaster's points of diversion to recharge basins, USGS gaging stations, and IEUA's recycled water discharges. The impact of Watermaster's diversions on discharge to the Prado Dam Reservoir is assessed at the point on Chino Creek where recycled water from the IEUA RP1 recycling plant discharges to Chino Creek¹ (see *Point of Discharge Estimation* on Figure 1). Estimated average daily discharge entering the Prado Dam Reservoir from Chino Creek is calculated from the average daily discharge measured at USGS gage 11073360 plus the average daily discharge from each of IEUA's recycled water discharge points (Carbon Canyon, RP1-Prado, and RP5). These discharges are summarized in rows 1 and 2 of Table 2a and are shown in detail in Appendices A1 and A2. The resulting daily discharge time history, summarized in row 3 of Table 2a and shown in detail in Appendix A3, approximates actual daily discharge in Chino Creek after Watermaster's diversions. Note that this estimation does not account for additional stormwater inputs generated by the Chino Creek drainage area located south of USGS gage 11073360. This area covers 23.75 square miles and represents about 26 percent of the total Chino Creek drainage. Thus, the relative impact of Watermaster's diversions is overstated.

The time history of stormwater and dry-weather discharge diversions is summarized in row 4 of Table 2a and is shown in detail in Appendix A4. When added together, the daily discharge time histories from Appendices A3 and A4 yield the approximate daily discharge time history in Chino Creek had Watermaster not diverted stormwater and dry-weather flows for recharge. The discharge time history without stormwater diversions is summarized in row 5 of Table 2a and is shown in detail in Appendix A5. The percent reduction in discharge entering the Prado Dam Reservoir relative to the estimated discharge without Watermaster diversions is summarized in row 6 of Table 2a.

The total discharge entering the Prado Dam Reservoir from Chino Creek during fiscal 2009/10 was estimated to be about 29,400 acre-ft, ranging from a low of about 1,500 acre-ft/month to a high of about 5,800 acre-ft/month. The total diversions from Chino Creek were estimated to be about 2,200 acre-ft. Most of the diversions occurred during the period of December through April and were coincident with the larger storm events of the year. About 7 percent of the total discharge in Chino Creek was diverted for recharge in fiscal 2009/10. Total discharge to the Prado Dam Reservoir is shown in Figure 2a as a stacked bar chart for monthly totals (acre-ft) and an x-y plot for the average daily discharge (cubic feet per second [cfs]). Figure 2a illustrates

¹ Note that the IEUA RP1 recycling plant has two discharge locations: one to Chino Creek (RP1-Prado) and one to Cucamonga Creek (RP1-Cucamonga).

that the relative magnitude of the stormwater diversions for recharge are small compared with the total estimated discharge entering the Prado Dam Reservoir. Figure 2a also shows that the vast majority of recharge results from just a few short-duration, high-volume stormwater events.

Cucamonga Creek

Figure 1 shows the location of significant points of recharge and discharge on the Cucamonga Creek tributary system, including Watermaster's points of diversion to recharge basins, USGS gaging stations, and IEUA's recycled water discharges. The impact of Watermaster's diversions on discharge to the Santa Ana River at the Prado Dam Reservoir is assessed at the point where the concrete-lined channel of Cucamonga Creek ends (see *Point of Discharge Estimation* on Figure 1). Average daily discharge entering the Prado Dam Reservoir from Cucamonga Creek is approximated as the average daily discharge measured at USGS gage 11073495. The estimated discharge time history is summarized in row 1 of Table 2b and is shown in detail in Appendix B1. Note that this estimation does not account for additional stormwater inputs generated by the Cucamonga Creek drainage area located south of USGS gage 11073495. This area covers 13.42 square miles and represents about 15 percent of the total Cucamonga Creek drainage. Thus, the relative impact of Watermaster's diversions is overstated.

The time history of stormwater and dry-weather discharge diversions is summarized in row 2 of Table 2b and is shown in detail in Appendix B2. When added together, the daily discharge time histories from Appendices B1 and B2 yield the approximate daily discharge time history in Cucamonga Creek had Watermaster not diverted stormwater and dry-weather flows for recharge. The discharge time history without Watermaster diversions is summarized in row 3 of Table 2b and is shown in detail in Appendix B3. The percent reduction in discharge entering the Prado Dam Reservoir relative to the estimated discharge without Watermaster diversions is summarized in row 4 of Table 2b.

The total discharge entering the Prado Dam Reservoir from Cucamonga Creek during fiscal 2009/10 was estimated to be about 37,600 acre-ft, ranging from a low of about 400 acre-ft/month to a high of about 11,400 acre-ft/month. The total diversions from Cucamonga Creek were estimated to be about 5,500 acre-ft. Most of the diversions occurred during the period of December through April and were coincident with the larger storm events of the year. About 13 percent of the total discharge in Cucamonga Creek was diverted for recharge in fiscal 2009/10. Total discharge to the Prado Dam Reservoir is shown in Figure 2b as a stacked bar chart for monthly totals (acre-ft) and an x-y plot for average daily discharge (cfs). Figure 2b illustrates that the relative magnitude of the stormwater diversions for recharge are small compared with the total estimated discharge entering the Prado Dam Reservoir. Figure 2b also shows that the vast majority of recharge results from just a few short-duration, high-volume stormwater events.

Day Creek

Figure 1 shows the locations of significant points of recharge and discharge on the Day Creek tributary system, including Watermaster's points of diversion to recharge basins and the confluence of the Day Creek with the Santa Ana River (see *Point of Discharge Estimation* on Figure 1). Average daily discharge to the Santa Ana River from Day Creek is simulated using the WLAM. The simulated daily discharge represents the discharge to the Santa Ana River without stormwater and dry-weather diversions for recharge. The discharge time history simulated by the WLAM is summarized in row 1 of Table 2c and is shown in detail in Appendix C1.

The time history of stormwater and dry-weather discharge diversions is summarized in row 2 of Table 2a and is shown in detail in Appendix C2. Subtracting the daily diversion time history of Appendix C2 from the daily discharge time history of Appendix C1 yields an estimated time history of average daily discharge from Day Creek to the Santa Ana River after Watermaster diversions.² This discharge time history is summarized in row 3 of Table 2c and shown in detail in Appendix C3. The percent reduction in discharge entering the Santa Ana River relative to the simulated discharge without Watermaster diversions is summarized in row 4 of Table 2c. Table 2c (row 5) also shows a summary of the discharge measured at USGS gage 11064600, the closest gage on the Santa Ana River upstream of the confluence with Day Creek (see Figure 1). The percent reduction in discharge from Day Creek relative to discharge in the Santa Ana River is summarized in row 6 of Table 2c.

Total discharge to the Santa Ana River from Day Creek during fiscal 2009/10 was estimated to be about 8,062 acre-ft, ranging from a low of 0 acre-ft/month to a high of about 3,553 acre-ft/month. The total diversions from Day Creek were estimated to be about 1,800 acre-ft. Most of the diversions occurred during the period of December through April and were coincident with the larger storm events of the year. About 17 percent of the total discharge in Day Creek was diverted for recharge in fiscal 2009/10. The percent reduction in discharge in Day Creek relative to discharge in the Santa Ana River, as represented at USGS gage 11064600, is about 1.5 percent. Total discharge is shown in Figure 2c as a stacked bar chart for monthly totals (acre-ft) and an x-y plot for average daily discharge (cfs). Figure 2c illustrates that the vast majority of recharge results from just a few short-duration, high-volume stormwater events.

San Sevaine Creek

Figure 1 shows the locations of significant points of recharge and discharge on the San Sevaine Creek tributary system, including Watermaster's points of diversion and the confluence of the San Sevaine Creek with the Santa Ana River (*Point of Discharge Estimation* on Figure 1). Average daily discharge to the Santa Ana River from San Sevaine Creek is simulated using the WLAM. The simulated daily discharge represents the discharge to the Santa Ana River without stormwater and dry-weather diversions for recharge. The discharge time history simulated by the WLAM is summarized in row 1 of Table 2d and shown in detail in Appendix D1.

The time history of stormwater and dry-weather discharge diversions is summarized in row 2 of Table 2d and shown in detail in Appendix D2. Subtracting the daily diversion time history of Appendix D2 from the daily discharge time history of Appendix D1 yields an estimated time history of daily discharge from San Sevaine Creek to the Santa Ana River after Watermaster diversions.² This discharge time history is summarized in row 3 of Table 2d and shown in detail in Appendix D3. The percent reduction in discharge entering the Santa Ana River relative to the estimated discharge of San Sevaine Creek without Watermaster diversions is summarized in row 4 of Table 2d. Table 2d (row 5) also shows a summary of the discharge measured at USGS gage 11064600, the closest gage on the Santa Ana River upstream of the confluence with San Sevaine Creek (see Figure 1). The percent reduction in discharge from San Sevaine Creek relative to discharge in the Santa Ana River is summarized in row 6 of Table 2d.

² Note that the WLAM does not simulate dry-weather flows on the Day Creek or San Sevaine Creek tributary systems. Thus, there will be dates where the simulated discharge to the Santa Ana River without diversions is zero even though measured diversions from Day Creek or San Sevaine were greater than zero on those same dates. For those dates where WLAM simulated discharge to the Santa Ana River without diversions is zero and diversions from Day or San Sevaine Creeks are greater than zero, the calculated average daily flow after diversions is set to zero because discharge cannot be a negative number.

Total discharge to the Santa Ana River from San Sevaine Creek during fiscal 2009/10 was estimated to be about 5,000 acre-ft, ranging from a low of 0 acre-ft/month to a high of about 2,800 acre-ft/month. The total diversions from San Sevaine Creek were estimated to be about 4,800 acre-ft. Most of the diversions occurred during the period of December through April and were coincident with the larger storm events of the year. About 38 percent of the total discharge in San Sevaine Creek was diverted for recharge in fiscal 2009/10. The percent reduction in discharge in San Sevaine Creek relative to discharge in the Santa Ana River, as represented at USGS gage 11064600, is about 3 percent. Total discharge is shown in Figure 2d as a stacked bar chart for monthly totals (acre-ft) and an x-y plot for average daily discharge (cfs). Figure 2d illustrates that the vast majority of recharge results from just a few short-duration, high-volume stormwater events.

Should you have any questions regarding the information contained herein, please call me or Samantha Adams at (949) 420-3030.

Respectfully,

Wildermuth Environmental, Inc.
